AI Tools

The tool that we all know and that is very famous, the ChatGPT, in previous semesters, when I was in the subject of "Object Oriented Programming", I remember that I was creating the user interface for my final project which was not "excellent" but it was something decent to deliver as a final project. After a few months, I used that same project to document it and I asked ChatGPT for help to improve the user interface, rereading the code now, I realize that the interface has not a great improvement, it is barely noticeable the improvement between the previous code and the new one. It is very easy to notice that when you ask for solutions in terms of graphical improvement, yes there are; but in terms of code level not so much. I would say that it is not complicated to use ChatGPT for the graphic but for the code, since the question must be very specific, even so the answer is very generic and does not give you the complete solution, in my words, it gives you what you need in a very general way. The usability attribute was not noticeable at all, although it seemed like it was because of the colors and images but it didn't really help any function other than being "nice and colorful". In my opinion I would say that maybe yes but it would be a long way to go, since in many occasions we think that the overall experience that users have when interacting with a computer system is sometimes predictable when it is not, the tools that use AI can sometimes be of great help or sometimes not do much.
